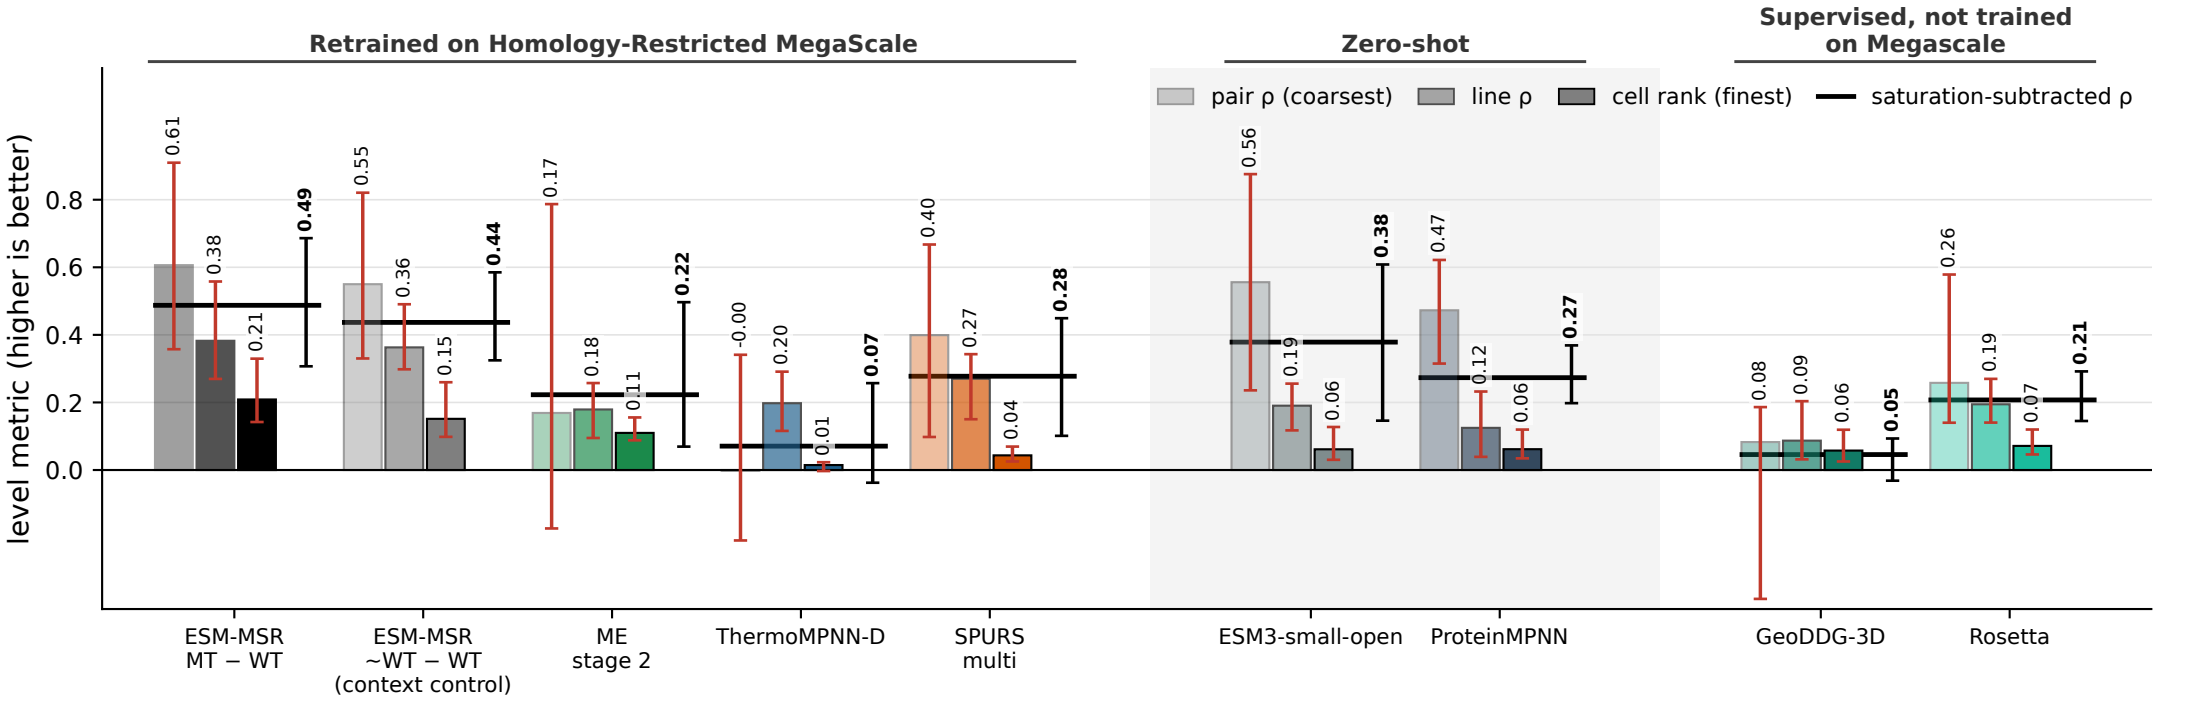
Test: epistasis predicted level by level, 12,455 doubles with both singles measured in 13 domains



GeoDDG-3D is trained on S8754 (ProThermDB + ThermoMutDB), not on Megascale.
Epistasis = the double-mutant prediction of one model minus the additive reading of another or of another head: ESM-MSR MT − WT and ~WT − WT; ME stage 2, ThermoMPNN-D, SPURS multi minus the same seed's singles; ESM3-small-open unmasked combined head minus its WT head; ProteinMPNN, GeoDDG-3D, Rosetta minus the sum of their singles. Seed means over the three seeds of the retrained models.
Intervals: 95% bootstrap over domains (the same resample for every model; the epistasis suite recomputed on each); the black dash is the saturation-subtracted ρ, with its interval on the protruding end.
