
Comparison of cell-level (identity-specific) epistasis metrics on the same models and 95% domain-bootstrap resamples:
(1) cell rank: double-centred within-column ranks of raw ddG_AB per complete block, averaged across blocks (saturation-invariant, but sensitive to single-mutant main-effect scale/spacing);
(2) cell ρ (block avg, cell_mag): Spearman ρ of global+pair+line-corrected residuals (c = r − r_row − r_col + r_pair) per complete block, averaged across blocks;
(3) cell ρ (pooled): single Spearman ρ pooled across all global+pair+line-corrected cells of all complete blocks;
(4) cell ρ (dG_add > 0): per-pair Spearman ρ of double-centred residuals restricted to unsaturated doubles (measured dG_additive > 0 kcal/mol).
